The subsequent slides (not including this slide) contain **draft** material proposed for an IEEE 802 tutorial on CTF (see [https://mentor.ieee.org/802.1/dcn/21/1-21-0030-00-lCne-ctf-ieee-802-tutorial-request-2021-05-21.pdf](https://mentor.ieee.org/802.1/dcn/21/1-21-0030-00-lCne-ctf-ieee-802-tutorial-request-2021-05-21.pdf)):

- The contents of the following slides are designed to show content as it would like in a final version.
- All contents in this slide set are subject to discussion, change/correction, removal and addition. Nonetheless, this slide set is intended to give a preview of the merged individual contributions for the IEEE 802 tutorial.

**Discussions and contributions are welcome!**
IEEE 802 Tutorial: 
Cut-Through Forwarding (CTF) among Ethernet networks

Johannes Specht, Jordon Woods, Paul Congdon, Lily Lv, Henning Kaltheuner, Genio Kronauer, Alon Regev
Overview

Cut-Through Forwarding (CTF) is a known method to improve the delay performance in bridged Ethernet networks.

CTF is already implemented in many commercial products and is therefore technically feasible. Standardizing CTF in IEEE 802.1 and IEEE 802.3 would enable interoperable implementations.

The goal of this tutorial is to motivate standardizing CTF. The tutorial introduces CTF on a technical level, explains application areas, markets and use-cases for CTF, and addresses aspects of standardizing CTF.
Disclaimer

This presentation should be considered as the personal views of the presenters not as a formal position, explanation, or interpretation of IEEE.

Per IEEE-SA Standards Board Bylaws, August 2020:

At lectures, symposia, seminars, or educational courses, an individual presenting information on IEEE standards shall make it clear that his or her views should be considered the personal views of that individual rather than the formal position of IEEE.

Introduction: Speakers
Jordyn Woods is a strategic technologist for Analog Devices Industrial Ethernet Technology Group (IET). IET enables seamless and secure connection of customer products across the entire landscape of Industrial IoT. Woods has 35 years of experience in the semiconductor industry. He is familiar with a variety of Ethernet-based Industrial protocols including Profinet, EtherNet/IP, as well as IEEE TSN standards. He is also a voting member of the IEEE 802 working group defining new Ethernet standards for Time Sensitive Networks and the editor of the IEC/IEEE 60802 Time-Sensitive Networking Profile for Industrial Automation.

Johannes Specht is a consultant and a researcher. His research area is the real-time traffic scheduling aspects of TSN. He holds a diploma in applied computer science and is currently finishing his PhD at the University of Duisburg-Essen (Germany). He has been the technical editor of the IEEE P802.1Qcr - Asynchronous Traffic Shaping (ATS) project, and an active technical contributor to several IEEE 802.1 TSN standardization projects on real-time traffic scheduling, reliability, fault tolerance, time synchronization, and configuration since joining IEEE 802.1 nine years ago. Johannes has been providing expert consulting to General Motors (USA) on using Ethernet for safety-critical applications since 2012. His professional career started in 2003 in the automotive industry, where he contributed to several projects on communication systems, testing, and functional safety.

Paul Congdon is a co-founder and is the Chief Technology officer (CTO) of Tallac Networks. He has over 34 years of experience in the networking industry and has become a widely esteemed inventor and leader in the networking industry. Prior to Tallac Networks, Paul was a Fellow at Hewlett Packard’s Networking and Communications Labs with responsibility for HP’s research in mobility, wireless and SDN network infrastructure. Paul has led, chaired, and is currently contributing widely to industry standards in the IEEE and IETF. Paul has a PhD in Computer Science from the University of California, Davis.

Henning Kaltheuner is Head of Business Development and Market Intelligence at d&b audiotechnik since December 2013. He knows the pro audio industry inside and out, having worked in positions ranging from Front of House to senior manufacturing roles. Before joining d&b Henning worked e.g. for brands like Riedel and Yamaha. Besides both his hands-on and managing experience in the pro audio and broadcast industry Henning’s main expertise is market research based on his master degree in psychology at University of Cologne with a specialization on media psychology and qualitative research. His work has concentrated on gaining insights into market trends, brand perceptions and customer expectations in the pro audio industry. Since 2004 a special focus for him has been on trends and expectations for network systems in the field of ProAV.

Alon Regev is a system architect fluent in both the hardware and software domains who has innovated in network communications for over 30 years. For the last 20 years Alon has worked at Ixia and Keysight Technologies. Alon has founded 2 companies and has over 60 patents granted. Alon has led, participated, and is contributing to multiple standardization efforts with a focus on Industrial and Automotive network systems, Time Synchronization and Time-Sensitive Networks. Alon is the chair of the Avnu testability task group, a voting member of IEEE 802.3, BSCS, California State University, Northridge (USA).
Introduction: Cut-Through Forwarding

Johannes Specht
TSN Context

Time-Sensitive Networking (TSN) Profiles (Selection and Use of TSN tools)

- Audio Video Bridging [802.1BA]
- Fronthaul [802.1CM/de]
- Industrial Automation [IEC/IEEE 60802]
- Automotive In-Vehicle [P802.1DG]
- Service Provider [P802.1DF]
- Aerospace [P802.1DP]

TSN Components

- Synchronization
- Reliability
- Latency
- Resource Management

Time synchronization:
- Timing and Synchronization [802.1AS-2020]
  (a profile of IEEE 1588)
- Hot Standby [P802.1ASdm]
- YANG [P802.1ASdn]

Bounded low latency:
- Credit Based Shaper [802.1Qav]
- Frame Preemption [802.1Qbu & 802.3br]
- Scheduled Traffic [802.1Qbv]
- Cyclic Queuing and Forwarding [802.1Qch]
- Asynchronous Traffic Shaping [802.1Qcr]
- QoS Provisions [P802.1DC]

High availability / Ultra reliability:
- Frame Replication and Elimination [802.1CB]
- Path Control and Reservation [802.1Qca]
- Per-Stream Filtering and Policing [802.1Qci]
- Reliability for Time Sync [802.1AS-2020]

Dedicated resources & API:
- Stream Reservation Protocol [802.1Qat]
- Link-local Registration Protocol [802.1CS]
- TSN Configuration [802.1Qcc]
- Foundational Bridge YANG [802.1Qcp]
- YANG for CFM [P802.1Qcx]
- YANG for LLDP [P802.1ABcu]
- YANG for 802.1Qbv/Qbu/Qci [P802.1Qcw]
- YANG & MIB for FRER [P802.1CBev]
- Extended Stream Identification [P802.1CBdb]
- Resource Allocation Protocol [P802.1Qdd]
- TSN Configuration Enhancements [P802.1Qdj]
- LLDV2 for Multiframe Data Units [P802.1ABdh]
- Multicast and Local Address Assignment [P802.1CQ]

Note: A ‘P’ in front of an ID indicates an ongoing Project.

CTF in the TSN Context

CTF is close to Preemption:
• Generic speed-up tool
• Needs the expertise of two IEEE 802 WGs: IEEE 802.1 and IEEE 802.3
Basic CTF Operation

CTF is an alternative forwarding method to Store & Forward (S&F) in Bridges

**Store & Forward**
IEEE Std 802.3-2018, IEEE Std 802.1Q-2018, and associated Standards

**Cut-Through Forwarding (CTF)**
Not standardized in IEEE 802.3 and IEEE 802.1;
One flavor of several different existing implementations

---

Enhanced delay performance
- Reduced residence times of frames in Bridges (“speed-up”).
- Reduced frame length dependent jitter/delay variation.

Challenges
- Forwarding and transmission of erroneous frames under reception:
  - Potentially to the wrong destination port(s) and/or traffic classes.
  - Limited handling options after subsequent late error discovery (e.g., FCS verification).
- S&F operation manifested in IEEE 802.1 and 802.3 Standards, at least to a certain extent.

Different flavors of CTF
- Forwarding to destination port(s): After lookup vs. after 64 octets
- Late error handling in destination port(s): Truncating vs. (just) marking such frames
- ...
- A good reason for standardizing CTF, regardless of the decisions which flavor(s) to standardize!
CTF Speed-up Analysis: Assumptions (1)

Purpose
• The following assumptions assemble a simplified model to focus on a simple speed-up analysis:
  • Some assumptions can be valid for some real systems, while being invalid for others.
  • The assumptions here are not intended as requirements or limitations for real systems with CTF.

Topology/Network
• Chain Network/Network segment
• Identical Link Speeds, Full-Duplex, negligible propagation delays
• CTF possible on all interconnections except from/to end stations (i.e., S&F at first and last hops)
• Strict Priority Transmission Selection Algorithm, optional with Enhancements for Scheduled Traffic

Errors
• Error free environment → no data corruption in frames
• However, errors, including late error handling, is addressed later in this tutorial
CTF Speed-up Analysis: Assumptions (2)

Traffic – Focus on Bounded Latency

- **High Priority (HP):** Focus of the Analysis
  - At most one stream sent by each end station, and each end station receives HP streams from at most one direction of the chain
  - Constant frame length\(^1\)
  - Periodic (same period for all streams)
  - Period < maximum end-to-end latency
  - Nominal transmission times at sending end stations

- **Low Priority (LP):** Background
  - Always Store & Forward
  - Interferes with HP traffic
    - Without preemption: 1542 octets (max. LP frame\(^1,2\))
    - With preemption: 155 octets (max. non-preemptible LP frame\(^1,3\))
CTF Speed-up Analysis: Math

\[
d_{SFF}^{\max} = (H + 2) \left( \max\{l_{HP}d_{Oct}, l_{Hdr}d_{Oct} + d_{LU}\} + d_Q \right) + \left( (H+1)l_{LP} + Hl_{HP} \right)d_{Oct}
\]

Maximum interference by crossing high priority traffic (\(l_{HP}\)) and crossing low priority traffic (\(l_{LP}\)). Dependent on the subsequently introduced communication schemes, either one or both types of interference exist or not (e.g., full TDM avoids both).

\[
d_{CTF}^{\max} = 2\left( \max\{l_{HP}d_{Oct}, l_{Hdr}d_{Oct} + d_{LU}\} + d_Q \right) + \frac{H(l_{Hdr}d_{Oct} + d_{LU} + d_Q)}{(H+1)l_{LP} + Hl_{HP})d_{Oct}}
\]

Separates the \(H\) interconnections (CTF) from the first and last ones (S&F). Note that, if the lookup finishes after frame completion during reception, then CTF provides no lower delay than S&F. The other way around, if the lookup is "fast enough", then CTF provides lower delays than S&F.

Lower percent values indicate higher end to end delay performance improvements of CTF over S&F.
Reasons for standardizing CTF in IEEE 802

Interoperable and deterministic data plane

- When to forward frames under reception
- Late error handling
  - Truncate erroneous frames?
  - Mark erroneous frames?
  - Do nothing?
- Distinguish CTF traffic from S&F traffic
  - TAGs, Addresses, Ports, ...?
- Behavior of existing 802.1 Bridge mechanisms for CTF traffic
  - Transmission selection algorithms?
  - Link speed transitions?¹
  - ...

Unified Management

- Elements
  - Configuration Parameters (e.g., enable/disable CTF)
  - Device properties (e.g., timing)
  - Status Variables (e.g., erroneous CTF frame counters)
- Required, for example, for automated, efficient and consistent configuration (e.g., centralized network controller [802.1Qcc-2018])

Application and limitations of CTF in Networks

- Quality of Service¹,²
- Security Considerations ¹
- Resulting Network Requirements/Recommendations

Use-Cases: Industrial Automation

Jordon Woods
Networking Requirements: Principal Data Path (Control Loop)

Principle data path between the controller and a device:

- The entities which are involved into the guaranteed latency transmission for the control loop are depicted
- Latencies for link layer control, bus interface, MACPHY are incurred at the controller and the device
- Combined store & forward, bridge delay and PHY delay accumulate at each hop in the network.
Networking Requirements: Summary

Industrial applications, such as machine control, are typically connected in long line configurations. For these installations, to minimize wiring cost and complexity, typical installation uses “daisy chain” where each node has (2) external switched ports and an internal port that goes to the end-node.

A common application is motion control where fast loop times are required. 125 µs cycle rate is common for 100 Mbps. Even lower rates (62.5µs/31.25µs ) are desired for 1 Gbps. To support this, low latency for messages through the network is a high priority.

Even Gigabit data rates are not sufficient to solve this problem. Combined store & forward, bridge delay and PHY delay exceed timing budgets. For instance, in a line topology of 64 hops, accumulated latency would exceed a 100 µs control loop even at Gigabit speeds.

These industrial automation systems often have environmental constraints (power, space, radiated emissions, etc.) which make lower data rates desirable. There is a desire in some applications to support brown-field wiring. Often, these devices are resource, power and cost-constrained. For these applications 100Mb/s rates are desired.
Why Line Topologies?

• Physical constraints make cabling for star topologies impractical
• The construction of the application naturally lends itself to point-to-point connectivity
• They are, after all, assembly “lines”
Use Case 2 - Redundancy (ring topologies)

- Typical topology for redundancy in industrial networks is a ring:
  - Inherently different packet latency on the network along the different routes
  - Depending on the setup, packet latency on the two paths can have extreme deviation
  - Depending on the allowed reception window of redundancy mechanisms, ring size is limited
  - For instance, for a 300 byte packet and 100 us packet deviation:
    - At 100 Mbit/s: the max. tolerable difference in the path is consumed in 4 hops
    - At 1 Gbit/s: the max. tolerable difference in the path is consumed in 34 hops
Industrial Network Growth

Industrial automation market > $123B in 2019

Connectivity portion is growing

- Fieldbus (58%), 7% growth
- Ethernet (38%), 20% growth
- Limited wireless adoption

With the advent of a common layer 2 (TSN), Industrie 4.0, China 2025, etc., strong growth is expected.

- Global industrial Ethernet market valued at USD $24B in 2016
- Expected to grow to $58.98 billion by 2022
- CAGR of slightly above 16.20% (2017 and 2022)

Use-Cases: Professional Audio/Video

Henning Kaltheuner, Genio Kronauer
ProAV perspectives

Ethernet is actually becoming the dominant media and control infrastructure in all **functional** Audio/Video applications

- Functional = Audio and Video serve a purpose within a relevant context

- ‘Classic’ ProAV applications:  
  (Performance oriented systems)
  - Live Concerts, shows, events (mobile, temporary)
  - Installations for live events in theatres, live clubs, concert halls, .... (fixed, permanently)

- Commercial installation:  
  (non- performance oriented systems)
  - Conference centers
  - Corporate buildings
  - Casinos, Hotels, Theme parks
  - Cruise Ships
  - Sport venues
  - Transportation
  - Smart venues
ProAV perspectives

Important trends:

• Traditional borders between applications disappear
  • **Venue multi-functionality** - One room/hall to serve many purposes (Club, Conf. room, Corp. event space, HoW, Musical, Cinema in one space)
    - Maximum of versatility expected
    - Minimum setup/conversion time
  • Audio and Video content / experience becoming part of many buildings
  • Hybrid event formats - ‘Live’ interaction of audience with content
    On – site or remotely
    - Multi-campus venue structures (HoW, Conference)
    - ‘Gamification’ means ‘real-time’ interaction

• Expectations for future ProAV systems go to an extreme of ‘intelligent’, very low latency networked digitalization.
ProAV perspectives

Everything will be networked – but so far everything is a compromise:

- ProAV doesn’t get the low latencies that are needed

- **Real-time ProAV applications have very similar requirements as industrial applications** *(see Industrial Automation use-cases and IEC/IEEE 60802)*
ProAV perspectives

Everything will be networked – but so far everything is a compromise:

• ProAv doesn’t get the low latencies that are needed

• A live music application compares well with an industrial automation process.
• Max. 2-3ms of latency through the entire signal chain can be tolerated.

• **BUT:**
  • This often includes cascades of networks
  • Signal capturing, processing, transmission requires time!

• Even for the self-contained ProAV applications network structures can not be fast enough.
ProAV perspectives

Everything will be networked – so far everything is a compromise:

• **Network latency has deep impact on ProAV system structures**

• **Example:** If network latency is 1ms and max. 3ms total end-to-end latency is accepted then the system structure is limited to 2 network connections within the signal path:

- Throughput latency:
  - Signal source: 0-100us
  - Network Path #1: 100us
  - DSP#1 (e.g. Signal processor): 100-200us
  - Network Path #2: 100us
  - DSP#2 (e.g. Mixer): 500us
  - Network Path #3: 100us
  - DSP#3 (e.g. 3D processor): 500us
  - Network Path #4: 100us
  - DSP#4 (e.g. Speaker processor): 100-200us
  - Network Path #5: 100us
  - Signal Receiver (e.g. amp): 100-500us

  = 2.2ms – 2.7ms Total end-to-end latency

• **Desired structure:** Ability to have multiple network paths within a signal path:

- Throughput latency:
  - Signal source: 0-100us
  - Network Path #1: 100us
  - DSP#1 (e.g. Signal processor): 100-200us
  - Network Path #2: 100us
  - DSP#2 (e.g. Mixer): 500us
  - Network Path #3: 100us
  - DSP#3 (e.g. 3D processor): 500us
  - Network Path #4: 100us
  - DSP#4 (e.g. Speaker processor): 100-200us
  - Network Path #5: 100us
  - Signal Receiver (e.g. amp): 100-500us

  = 1.8ms – 2.7ms Total end-to-end latency

• This ability deeply determines ProAV product concepts, system and business structures
• @100us per network path enable distributed hybrid signal processing environments
ProAV perspectives

From Stonehenge to 21st century:

- Most public or functional buildings include PA/VA systems (Public Address / Voice Alarm)

- Subject to fire/security regulations
- System / component status must be monitored / ensured
- Full redundancy required (A/B system structures)
- So far almost no digitalization!
- 99% Daisy-chained structures
ProAV perspectives

From Stonehenge to 21nd century:

- Most public or functional buildings include PA/VA systems (Public Address / Voice Alarm)

Future expectations:
- Full remote monitoring of every component
- Flexible integration with other AV/Event systems
- Intelligent zoning

Requirement:
- Consistent low latency independent from length of chain for ensuring consistent performance
- Addressability per component
- Integrating other functionality (microphones, immersive sound, smart ceilings, interactive functions)
ProAV perspectives

From Stonehenge to 21st century:

- Most public or functional buildings include PA/VA systems (Public Address / Voice Alarm)

Forecast:
- We will have these structures in all functional buildings: Corporate, Government, Education, Hotel, Leisure, HoW, Airports, Transportation ……
- # of components (end stations): Cruise Ship: 50,000
  Casino: 12,000
  Airport: 10-30,000
- So far the network has been the bottleneck to full building integration with audio and video content
- There are many other use-cases for such daisy-chained structures in ProAV.
- CTF can be enabling technology
ProAV perspectives

Conclusions:

• ProAV becomes a part of many contexts in many different buildings
• Markets for intelligent systems with expanded functionalities are expanding fast
• Current NW topologies and properties have hindered full digitalization of building and event system structures
• Latency is critical to all live and/or interactive applications and to consistent performance in spaces with distributed systems.
• Considering cascaded network structures in many system architectures and requirements for real-time interactive systems a latency of roughly 100us over up to 100 hops seems an optimal design.
• However: < 100us for 50 hops could very well be a reasonable target.
• These numbers count for 1GBit/s. For 100MBit/s higher latencies can be considered (tbd).
Use-cases: Data Center Networks

Paul Congdon, Lily Lv
High Performance Applications Growth in the Data Center

High Performance Computing (HPC), AI (Artificial Intelligence)/Big Data and Cloud Computing are hot growth areas.

The convergence of these 3 areas is currently a trend in the data center.

- HPC is available as a cloud service in many public offerings (AWS, Azure, Alibaba etc); growing 17.6% CAGR (Compound annual growth rate) , 2.5 times faster than on-premise HPC.
- HPDA (High performance data analytics) and HPC-based AI are fast emerging markets, with 16% and 31% CAGR respectively.

Source: Hyperion Research, November 2020
High performance applications are driving change in data center, putting pressure on end-to-end latency.

- System scale is increasing significantly, with much more end points and a larger network.
- Synchronization in large parallel applications is critical to job completion time.
- New hardware architectures, such as server disaggregation, require extremely low-latency fabric.
Latency is Critical in Data Center Networks (2)

New technologies are emerging to reduce system latency.

• **RDMA (Remote Direct Memory Access)**
  • RDMA enables direct memory access from one server to another, bypassing the TCP/IP stack handling in OS.
  • RDMA runs over InfiniBand or Ethernet.
    • InfiniBand, like Ethernet, is a networking technology, but customized for high throughput and low latency.
  • RDMA improves message transfer time by 5x compared with TCP/IP.
Latency is Critical in Data Center Networks (3)

New technologies are emerging to reduce storage latency.

- **Faster storage media**
  - Persistent storage latencies are approaching memory latencies with the latest Storage Class Memory (SCM) technology.

- **NVMe (Non-Volatile Memory express)**
  - NVMe is a storage interface specification defining communication between host software and PCIe SSD.
  - “The NVMe specification was designed from the ground up for SSDs. It is a much more efficient interface, providing lower latency, and is more scalable for SSDs than legacy interfaces, like serial ATA (SATA).”
    
    (https://nvmexpress.org/)
  - NVMeoF (NVMe over Fabrics) enables “networked” fast storage (SSD/SCM), however without networking enhancements, the network becomes the largest part of end-to-end latency.

**Network latency becomes the bottleneck!**
Latency is Critical in Data Center Networks (4)

Types of latency in data center networks: dynamic and static

**Dynamic latency** = queuing delay + retransmission delay

- Mainly caused by congestion
  - In-cast congestion from parallel applications.
  - In-network congestion from ineffective load balancing.

**Static latency** = switch forwarding + packet processing + link latency

- Impacted by forwarding table lookup delay, frame reception delay (if store and forwarding) and switching delay
- Impacted by header processing and packet modification
- Propagation delay impacted by distance and speed

• Dynamic latency is the major component and attracts a lot of the industry’s attention: See
  • 802 Nendica - The Lossless Network for Data Centers - [https://mentor.ieee.org/802.1/dcn/18/1-18-0042-00-LCne.pdf](https://mentor.ieee.org/802.1/dcn/18/1-18-0042-00-LCne.pdf)
  • 802 Nendica - Intelligent Lossless Data Center Networks - [https://mentor.ieee.org/802.1/dcn/20/1-21-0004-00.pdf](https://mentor.ieee.org/802.1/dcn/20/1-21-0004-00.pdf)

• However, Static latency becomes significant in high performance scenarios, such as HPC.
Benefits of Cut-Through Forwarding in the HPC Networks

HPC network operates at the nanosecond level
- E2E network latency is only several micro-seconds.
- Per hop latency is required as low as possible, hundreds of nano seconds, or even lower.

CTF is applicable in the HPC network
- Traffic loads can be predictable, leading to congestion avoidance techniques in switches.
- Data center topologies are well structured with similar type of switches.

Regular Topologies: Two typical HPC networks

**Fat Tree** is a rearrangeably non-blocking structure, which provides an oversubscription ratio of 1:1 to all servers.

**Dragonfly** is a well-balanced network with no oversubscription.
InfiniBand is the ‘first-choice’ in HPC Today (1)

Although 51% of the TOP500 supercomputers use Ethernet fabrics, InfiniBand is the dominant interconnect in TOP100.
InfiniBand is the ‘first-choice’ in HPC Today (2)

InfiniBand switch per hop latency is much lower than Ethernet

- Ethernet switching chipset latency can be greater than 100s of ns.
- Latency increases with frame size using store-and-forward.
- InfiniBand switching chipset latency can be less than 100ns.
- Cut-through is an important feature for InfiniBand to keep per hop latency low.

Ethernet needs CTF to further penetrate HPC

Ethernet has great opportunity to become more competitive in HPC market.

• TOP 500 shows Ethernet Interconnects already takes the largest share (51%)
• Ethernet has its own advantages
  • Ethernet is ubiquitous technology.
    • Cost-effective solution
    • Relatively easy to deploy and manage
    • Leading technology development
  • Ethernet provides large bandwidth connectivity
    • up to 400G, 100G for single lane
    • towards 800G, 200G for single lane

The obvious gap of Ethernet is latency
• Per hop latency gap is significant compared with InfiniBand
• CTF is a good method to improve per hop latency
Summary: Goals and Objectives
Summary: Goals and Objectives

The delay performance needed by the use-cases requires bridges to start frame transmission before complete reception (core principle of CTF):

- Preemption is no alternative to CTF
  - Preemption vs. CTF
    - Preemption: Reduces delays critical frames experience from other interfering frames.
    - CTF: Reduces delays of the critical frames themselves. (regardless whether interference by other frames is present or not)
  - Nonetheless, it is desirable to combine CTF with protocols from existing IEEE 802.1/802.3 Standards, including preemption.

- Higher link speeds are no alternative to CTF
  - Inapplicable where lower link speeds are desirable
    → Cost, environmental constraints, brown field installations (Industrial Automation)
  - Even at high link speeds, the delay performance enabled by CTF is needed (DCN)

- Different topologies are no alternative to CTF
  - Inapplicable where daisy chain and ring topologies are inevitable
    → Cost, physical constraints/pre-defined structures (Industrial Automation)
  - Even in optimized topologies, the delay performance enabled by CTF is needed (DCN)

→ Existing IEEE 802.1/802.3 Standards do not provide this performance.

→ Standardizing CTF is desirable to enable a common management approach and ensure interoperability.
IEEE 802.1 Considerations

Johannes Specht
Proposed Location in IEEE 802.1 Standards

Separate IEEE 802.1 base Standard

- **Single document**
  Avoids distribution of CTF across multiple existing base Standards, as it would be the case with multiple amendment projects.

- **Exclusion, inclusion/re-use and adjustment of existing protocols**
  - Existing protocols not referred to are basically beyond specification.
  - **If no adjustments for CTF are needed:**
    - Inclusion by reference (e.g., “as specified in x.y.z of IEEE Std 802.1Xxx-20XX”) can be sufficient.
  - **If adjustments for CTF are needed:**
    - Additional description of the differences can be sufficient.
    - Adjustments apply for CTF only; no side effects on existing protocols in absence of CTF support.

CTF in Networks: Application and Limitations

The Basic Issue

- Erroneous frame under reception are forwarded to the wrong destination port(s), associated with the wrong traffic class, or both.

Option: “Header CRCs”

- Add CRCs over frame headers, forward only after verification to avoid wrong forwarding decisions.
- Several issues (e.g., compatibility/interoperability, frame overheads, loose header definition).

Option: Analyze

Identify the resulting issues and analyze these issues individually.

- Circulating frames
  - Erroneous frames can circulate for “for a while” in topological loops.

- Additional congestion
  - Erroneous frames can cause additional congestion for other traffic in transmission ports.

- Security/Privacy
  - Payload of erroneous frames become visible on links where it shouldn’t be seen.

Could be analyzed during Stds activities ...
CTF in Networks: Circulating Erroneous Frames

Issue

Erroneous frames can circulate for “for a while” in topological loops.

Goal

Solution(s) depend on the definition of a goal:

An erroneous frame shall circulate longer than one round in a topological loop if FCS verification can discover the error in this frame.

Solutions (Alternatives)

1. One hop with S&F-only for all traffic in each topological loop (robust/default choice).
2. Constrained FDB setups, namely explicit unicast/multicast entries only, assuming a frame experiences corruption at most on one link.
3. Long loops, combined with frame truncation in Bridges and upper bounds on frame lengths.

Symbols

- Store & Forward (S&F)
- Cut-Through Forwarding (CTF) for explicit streams
- Point-to-Point Full Duplex Link
- Bridge
- End Station
- Explicit stream of E1
- Explicit stream of E2
- Explicit stream of E3
- Other/Background traffic (always S&F)
CTF in Networks: Additional Congestion

Issue

Erroneous frames can cause additional congestion for other traffic in transmission ports.
- Extra delays by additional interference
- Bandwidth reduction

Solutions

1. If applicable¹, usage of disjoint redundant paths via FRER².
2. If applicable³, usage of Per-Stream Filtering and Policing (PSFP) functions⁴.
3. Planning for additional interference/bandwidth usage.
4. Frame truncation of erroneous frames.

Symbols

- Store & Forward (S&F)
- Cut-Through Forwarding (CTF) for explicit streams
- Point-to-Point Full Duplex Link
- Bridge
- End Station
- Explicit stream of E₁
- Explicit stream of E₂
- Explicit stream of E₃
- Other/Background traffic (always S&F)

1) Disjoint redundant paths can be unacceptable for some systems (e.g., due to cost reasons).
3) The planning required to properly configure PSFP can be unacceptable for some systems.
4) Standardized in IEEE 802.1Q-2018.
## CTF in Networks: Security/Privacy

### Issue

Payload of erroneous frames become visible on links where it shouldn’t be seen\(^1\).

### Solution

Dependent on the security under consideration.

An outline of a potential model on the next slides
CTF in Bridges: Initial Feature Set

• **Required:**
  1. 802.1Q\textsuperscript{1}：“Basic” VLAN/MAC Bridge operations [initial text in 5.4 and 5.12 of IEEE Std 802.1Q-2018]
  2. Fallbacks from CTF to S&F (i.e., to the behavior standardized in IEEE 802.1 Stds)
  3. Late error handling for CTF

• **Options/within specification:**
  1. 802.1Qci\textsuperscript{1}: Per-Stream Filtering and Policing (PSFP)
  2. P802.1Qcz\textsuperscript{1}: Congestion Isolation (CI)
  3. 802.1Qbv\textsuperscript{1}: Enhancements for Scheduled Traffic (EST)
  4. 802.1Qaz\textsuperscript{1}: Enhanced Transmission Selection (ETS)
  5. 802.1CB\textsuperscript{1}: Frame Replication and Elimination for Reliability (FRER)
  6. 802.1Qbu\textsuperscript{1}: Preemption

---

1) With adjustments for CTF, as necessary.

---

**Common Elements (Superset):**
- Stream Filters
- Maximum SDU size filtering
- Stream Gates
- MEF 10.3 Flow Meters

**Common Element:**
- Transmission Gates
CTF in Bridges: Relay with CTF support

Extends the behavior of the already standardized model

- Frames pass through processing stages of the relay, with the following additions for CTF:
  - Passing of incomplete frames (i.e., frames under reception).
  - Frames remain visible after being passed to the next stage.
- Stalling incomplete frames
  Waiting for more received data of an incomplete frame before passing it to the next stage.
- Fallbacks to S&F
  Stalling frames until completion before passing to subsequent processing stages.
- Late errors
  Error causes and handling for frames under transmission during reception, both from different processing stages.

Enabling/disabling CTF

- Configurable per reception Port (the entire Port).
- Configurable per transmission Port per traffic class, if supported by this traffic class.

Traffic separation (co-existence of S&F and CTF)

- Priority from VLAN-Tags or via IPV assignment (part of “Flow metering”).
- Forwarding and queuing in different ports (FDB) and different traffic classes (via the decoded priority).
CTF in Bridges: Fallbacks to S&F

1. On the main relay path
   1. CTF reception is disabled on a reception Port
   2. CTF is disabled/unsupported by a traffic class on a transmission Port
   3. No matching filtering entry in the FDB (i.e., flooding)
   4. Association of a frame under reception with a FRER recovery function
   5. Slow-to-fast link speed transitions
   6. Frame length changes (e.g., TAG removal)

2. Leaving the main relay path
   1. To Higher Layer Entities
   2. FDB for learning

3. Implicit
   1. Interfering frames

---

Bridge Port Receive
Active topology enforcement
Ingress filtering1
Frame filtering
Egress filtering1
Flow metering2
Individual Recovery3
Sequence Recovery3
Sequence Encode3
Active Stream Identification3
Queue management
Transmission selection
Filtering Database
Reception Port State
Transmission Port State
1) Not present in MAC Bridges
2) Not present if PSFP or CI is unsupported
3) Not present if FRER is unsupported
CTF in Bridges: Late Errors

1. Causes
   1. Errors discovered by FCS verification
   2. Maximum SDU size filtering limit reached during reception
   3. Stream gates transition to closed state
   4. Color of flow meters transitions to red
   5. Frame exceeds the maximum SDU size of transmission gates

2. Handling
   1. Treat late errors as end of the associated frame maximum SDU size filtering, stream gates and flow meters.
   2. Remove the frame from all queues, at least if not under transmission.
   3. Truncate the end of frame, if possible.
   4. Mark the end of erroneous frames (e.g., with a special FCS).

---

1) In contrast to stream gates, it appears reasonable to not consider closing EST transmission gates during ongoing transmission as a late error (see 8.6.8.4 of IEEE Std 802.1Q-2018).

---

July 7, 2021
802.1 Considerations: Summary

This section covered 2 aspects:

• Addressing issues introduced by CTF
• The outline of a proposal for a potential future 802.1 Standard for CTF

It has been demonstrated that solutions for the issues exist, primarily on the network level.

Part of a potential future IEEE 802.1 Standard for CTF could be the following:

• The aforementioned solutions
• An extended version of the existing behavioral bridge relay model, with
  • fallbacks to the already standardized model and
  • extensions to support CTF in general and to allow late error handling.

Part of the proposal itself is to consider a single base standard for potential future 802.1 standards development activity instead of multiple amendments:

• Lightweight
• Centralized
• Compatibility retained in absence of support for CTF
IEEE 802.3 Considerations

Alon Regev, Johannes Specht
Problem Statements: Introduction

Background
• It is intended to move forward towards standardizing CTF in IEEE WG 802.1.
• We now dive into 802.3 and its interface with IEEE 802.1.

Potential Problem Summary
It is unclear whether particular elements of the MAC are in conflict with CTF at all. If yes, it is unclear how these conflicts can be resolved. Aspects identified so far:
1. Frame-level synchronous operations of the MAC service interface.
2. Invalid MAC frame handling, in particular in presence of the optional MAC Control sublayer.
3. The minimum frame size.
4. Normative statements are not always clear (where the style guidelines are not strictly followed).

Refinement
• The subsequent slides detail these aspects further.

IEEE 802 Tutorial: Cut-Through Forwarding (CTF) among Ethernet networks

July 7, 2021

62
IEEE 802.3 Considerations: MAC Service Interface

Background

• The MAC service interface is specified in IEEE Std 802.1AC-2016 making use of ISO/IEC 10731:1994 [3.2 and 13.1 of IEEE Std 802.1AC-2016].

• A service primitive is to be regarded as taking place as an instantaneous event [6.2, 7.2, and Figure 5 of ISO/IEC 10731:1994], which appears to be the case at least in IEEE Std 802.3-2018 [Figure 1-3 of IEEE Std 802.3-2018].

• Moreover, it appears that the ordering relationship between service primitive invocation and the precise specification of CSMA/CD MAC method and precise specification of MAC method of the simplified full duplex MAC suggest a sequential ordering between service primitive invocation and associated Pascal procedure call of [Figure 4-6, Figure 4-7, Figure 4A-3, Figure 4A-4 of IEEE Std 802.3-2018] based on associated state diagram conventions:

  Labels on transitions are qualifiers that must be fulfilled before the transition will be taken [1.2.1 of IEEE Std 802.3-2018].

  Each primitive has a set of zero or more parameters, representing data elements that shall be passed to qualify the functions invoked by the primitive [1.2.1.1 of IEEE Std 802.3-2018].

Concern

• It is not clear if the MAC service interface and the relationship to the precise MAC specifications allow Cut-Through Forwarding

• However, implementations are conformant so long as their externally visible behavior is identical to the model...
IEEE 802.3 Considerations: Implementation vs. Model

Background

IEEE Std 802.3-2018 differentiates between an implementation and the model in state machines and the procedural models:

- It is important to distinguish, however, between the model and a real implementation. The model is optimized for simplicity and clarity of presentation, while any realistic implementation shall place heavier emphasis on such constraints as efficiency and suitability to a particular implementation technology or computer architecture [4A.2.2 of IEEE Std 802.3-2018].

- It is the functional behavior of any unit that must match the standard, not its internal structure. The internal details of the model are useful only to the extent that they specify the external behavior clearly and precisely [1.2.1 of IEEE Std 802.3-2018].

- It is the behavior of any MAC sublayer implementations that shall match the standard, not their internal structure. The internal details of the procedural model are useful only to the extent that they help specify that behavior clearly and precisely [item b) in 4.2.2.1 and 4A.2.2.1 of IEEE Std 802.3-2018].

- The handling of incoming and outgoing frames is rather stylized in the procedural model, in the sense that frames are handled as single entities by most of the MAC sublayer and are only serialized for presentation to the Physical Layer. In reality, many implementations will instead handle frames serially on a bit, octet or word basis. This approach has not been reflected in the procedural model, since this only complicates the description of the functions without changing them in any way. [item c) in 4.2.2.1 and 4A.2.2.1 of IEEE Std 802.3-2018].

Observations

- The requirement for implementations is conformance to the externally visible behavior, not the specified structure, in certain areas of IEEE Std 802.3-2018 (but not all).

- It seems to be a statement of fact that many implementations would not be limited to the S&F operation implied by the MAC service interface.
IEEE 802.3 Considerations: Invalid MAC frames

Background

- During reception, the contents of invalid MAC frames (e.g., frames that would fail FCS verification) shall not be passed to LLC and MAC control sublayers [3.4 of IEEE Std 802.3-2018].
- There are other similar statements in IEEE Std 802.3-2018, although not using normative language (e.g., clause 2.3.2.3).
- The Pascal pseudocode (clause 4.2.9) and state machine (4.3.2.2) DO pass invalid MAC frames to higher layers.
- The MAC control sublayer is optional and located between MAC client (i.e., Bridge) and MAC transparently [4.1.1 and 4A.1.1 of IEEE Std 802.3-2018]. It is thus on the path from ingress to egress in a Bridge. In contrast, the LLC is not on this path [clause 6 in IEEE Std 802.1Q-2018] and excluded from further consideration.

Concern

- The requirement stated in 3.4 of IEEE Std 802.3-2018 is normative, but it appears to be a requirement for the model specified in IEEE Std 802.3-2018 (not for implementations).
- Implementations of the associated state machines [clause 31 of IEEE Std 802.3-2018] only need to match the external visible behavior, not the internal structure (previous slide).
- However, in the case this requirement does actually apply for implementations, it could imply a conflict if MAC control sublayer(s) are present.
IEEE 802.3 Considerations: Minimum Frame Size

Background

The minimum frame size of 64 octets is required for CSMA/CD operation of a CSMA/CD MAC [clause 4 IEEE Std 802.3-2018] and by the simplified full duplex MAC [clause A4 IEEE Std 802.3-2018].

Observations

• Both clause 4 and 4A MACs enforce a 64 octet minimum frame size on both Rx (smaller frames discarded) and Tx (smaller frames padded) [ReceiveLinkMgmt in 4.2.9 and 4A.2.9 of IEEE Std 802.3-2018] [dataSize definition in 4.2.7.1 and 4A.2.7.1 of IEEE Std 802.3-2018].
• The MAC merge sublayer is likewise ensuring that the minimum frame size constraint requirement is satisfied [Figure 99-4, 99.3.5 and 99.4.4 of 802.3-2018].

Concern

• If a frame is forwarded before 64 octets are received...
  • On the Rx side, forwarding a frame before 64 octets are received may violate the 802.3 MAC RecieveLinkMgmt procedure in clause 4.2.9 if the received frame is an undersized fragment (in which case the frame should have been dropped)
  • On the Tx side, padding a forwarded frame to 64 octets may delay further frames. This could be additive if multiple such fragments are encountered.
  • Conversely, if forwarded frames are not padded to 64 octets, this may be a violation of the 802.3 MAC clauses 4.2.3.3 and 4A.2.3.2.4.
  • Forwarding frames only when at least 64 octets are received may not meet latency requirements of some markets
IEEE 802.3 Considerations: Summary

- Cut-Through Forwarding involves layers spanning both IEEE 802.3 and IEEE 802.1
- There are open questions regarding on items in IEEE 802.3 that apply to Cut-Through Forwarding including
  - The MAC service interface
  - Invalid MAC frame handling
  - MAC control frame interactions
  - Minimum frame size
- IEEE 802.3 and IEEE 802.1 working together will yield the best results as the requirements and interfaces will be understood by both sides
Call for Actions

Johannes Specht
Summary of this Tutorial

• The goal of this tutorial is to motivate standardizing CTF in IEEE 802.1 and IEEE 802.3.
• CTF is already implemented in many commercial products and is therefore technically feasible!
• There are different flavors of CTF found in such implementations, and standardizing CTF in IEEE 802.1 and IEEE 802.3 would enable interoperability.
• There are present and future use-cases for CTF at least in the following markets:
  • Industrial Automation
  • Professional Audio/Video
  • Data Center Networks
• There are several aspects that need to be considered by IEEE WG 802.1 and IEEE WG 802.3 and discussed towards standardizing CTF.
Call for Actions

Moving Forward Proposal

Joint Work & Coordination (initial)

Joint Work & Coordination (ongoing)

IEEE 802.1

IEEE 802.3

Joint work & coordination

• CTF needs the expertise of two IEEE 802 WGs.
• It appears vital to have some level of joint work & coordination on technical aspects and logistics (interfaces, meetings, etc.).
• A possible forum for initial joint work & coordination: IEEE 802 Nendica.

Administrative discussion (separate meeting)

• Topics
  • Which pre-standards activities can and should be done in a (significant) initial joint work & coordination phase?
  • What are the logistics?
  • ...
• Meeting identified to plan followup: IEEE 802 Nendica weekly call schedule for August 5, 2021 09:00-11:00 ET (tentatively), pending finalization on July 20, 2021.

→ If you are interested in this discussion you are very welcome!
