Abstract

The support of people motion with blocking of signal paths (channel dynamics) is currently an open issue in the TGad channel model [1]. To overcome this we present simulations of the time-variant 60 GHz channel based on ray tracing, a random walk model and a diffraction model. The results could be easily included in the channel model document [2] as a further statistic.
Methodology

Ray Tracing

Random Walk Model

Diffraction Model

Set of time variant channel realizations

Channel Statistics
Diffraction Model

- Assuming Person as „Multiple Edges“
- Electric field strength calculation based on Fresnel Integral:

\[
\frac{E_d}{E_0} = \frac{1 + j}{2} \int_\nu^\infty \exp(-j \pi t^2) dt
\]

\[
mit \nu = h \sqrt{\frac{2(d_1 + d_2)}{d_1 d_2}}
\]

- Loss:

\[
G_d (dB) = 20 \log \left| \frac{E_d}{E_0} \right|
\]

- Good agreement between this simple model and measurements
Ray Tracing Simulations

- STA-AP Scenario from [2]

- AP position fixed

- STA positions uniformly distributed on the table
  - Simulated: 1071 STA positions

- Result:
  - Each ray represents one cluster (cf. [2])
  - 1071 CIR for the static scenario
  - Categorized Rays (Table 2 from [2])
    - LOS
    - 1st order
    - 2nd order
Random Walk Model

• **Simulation Parameters**
  
  - 1 Person walking around the table
    - Random Walk with preference direction
  
  - Speed \( v = 1 \text{m/s} \)
  
  - Step size: 60 cm
  
  - Person assumed as cuboid:
    - \( 0.45 \text{m} \times 0.15 \text{m} \times 1.70 \text{m} \)
  
  - Time resolution: 10 ms
  
  - Simulation Time: 30 s
  
  - Apply diffraction model to the ray tracing results

\[ \Rightarrow 3001 \text{ different time-variant CIRs for each of the 1071 STA positions} \]
Simulation Example for Random Walk
Example Results

Temporal variation of the diffraction Gain of the four 1st order reflected rays for a fixed STA position on the table.
Statistics

1. Number of blocked clusters
   - Based on pure „blockage approach“
   - Full blockage if ray intersects person
   - 2 categories (1st & 2nd order)

2. Blockage probabilities for single clusters
   - Based on diffraction model
   - Full blockage if ray is attenuated by more than 2 dB
   - 2 categories (1st & 2nd order)

3. Amplitude distribution
   - Based on diffraction model
   - Attenuation due to diffraction
Number of blocked clusters - 1

- 1071 x 3001 = 3,214,071 channel realizations
- In 99.99 % of the realizations the LOS link was NOT blocked!

- 1st order reflections from walls

Blockage Rate of single clusters

- The blockage rate of single clusters is calculated as the ratio of the duration of blockage and the simulation time (relative blockage time).

- In 99.99% of the realizations the LOS link was NOT blocked!

- For the four 1\textsuperscript{st} order reflections and the eight 2\textsuperscript{nd} order reflections pdfs are given:
Amplitude distribution of attenuated paths

- Only attenuated paths taken into account ($E_d/E_0 < -2$ dB)
- Otherwise the amplitude distribution would be nearly Dirac shaped at $E_d/E_0 = 1$ (0 dB), because the single path is not blocked most of the time
Conclusion

We propose to introduce the channel dynamics into the TGad channel document based on the presented simulation results. From this data it is possible to extract statistics about the total number of blocked clusters, about the blockage rate of single clusters or about the amplitude distribution of single clusters. These statistic can be included in the channel model in an adequate way.
